

about

What is climometer?

Climometer is a web app designed to improve access to climate data and predictions.

Scientists are constantly measuring climate and making predictions about the future, but their results are mostly kept in technical products that can be difficult to access or interpret.

To better understand how climate change can affect **you**, climometer gives predictions about your home, or any other part of the world.

It estimates the vulnerability of individual properties to climate change, in terms of their livability and potential damage.

Where do our data come from?

Climometer uses data from the latest models published by scientists and scientific institutions. Information about the data sources can be found [here](#).

Our algorithms to estimate change in livability and potential damage from climate change are open source and can be viewed and modified [here](#).

What can I do about climate change?

[This page](#) contains links to resources about what you can do to help curb climate change.

You can also sign our [e-petition](#) which will be sent to the Australian Government to demand urgent action on greenhouse gas emissions.
